The orthodoxy

- SFGs are not treated as interesting mathematical objects per se.
- Formal analysis typically mean translation into a “lower-level” formalism like systems of linear equations.

The Calculus of SF Diagrams

Circuit diagrams of Circ are generated by the grammar

$$\begin{aligned}
 c, d ::= & \boxed{\bullet} \mid \boxed{\bullet} \text{ (with a semi-circle on the right)} \mid \boxed{k} \mid \boxed{x} \mid \boxed{\text{AND}} \mid \boxed{\text{OR}} \mid \\
 & \boxed{\bullet} \text{ (with a semi-circle on the left)} \mid \boxed{\bullet} \text{ (with a semi-circle on the right)} \mid \boxed{k} \mid \boxed{x} \mid \boxed{\text{AND}} \mid \boxed{\text{OR}} \mid \\
 & \square \mid \square \text{ (with a horizontal line)} \mid \square \text{ (with a vertical line)} \mid \boxed{c} \boxed{d} \mid \begin{array}{c} \boxed{c} \\ \vdots \\ \boxed{d} \end{array}
 \end{aligned}$$

We can represent (orthodox) signal flow graphs as circuit diagrams:

Structural Operational Semantics

The operational semantics $\langle c \rangle$ is the set of all traces starting from an initial state for c (i.e. one where all the registers are labeled with 0).

Example

Denotational Semantics

The semantics $[[\cdot]]$ maps a circuit to a linear relation between stream vectors

Axiomatisation of $[[\cdot]]$

The equational theory of *interacting Hopf algebras* (IIIH):

- $\{\text{multiplication}, \text{comultiplication}\}$ and $\{\text{comultiplication}, \text{multiplication}\}$ form two commutative monoids.
- $\{\text{comultiplication}, \text{multiplication}\}$ and $\{\text{multiplication}, \text{comultiplication}\}$ form two commutative comonoids.
- monoid-comonoid pairs of different colors form Hopf algebras.

- monoid-comonoid pairs of the same color form Frobenius algebras.

- scalars and delays have formal inverses.

Soundness and Completeness

$$[[c]] = [[d]] \iff c \stackrel{\text{IIIH}}{=} d$$

Full Abstraction

Theorem (?)

For any c and d in Circ

$$\llbracket c \rrbracket = \llbracket d \rrbracket \iff \langle c \rangle = \langle d \rangle$$

Not true in general.

The denotational semantics is *coarser* than the operational semantics.

Theorem

For any c and d in Circ **deadlock and initialisation free**

$$\llbracket c \rrbracket = \llbracket d \rrbracket \iff \langle c \rangle = \langle d \rangle$$

Realisability

In presence of deadlocks or initialisation, we cannot determine directionality of the flow.

A trace for these circuits cannot be thought as the execution of a state-machine.

Realisability

In presence of deadlocks or initialisation, we cannot determine directionality of the flow.

A trace for these circuits cannot be thought as the execution of a state-machine.

However, all the circuit diagrams can be put into an executable form using the equational theory \equiv .

Realisability Theorem

For any circuit c of Circ there exists d deadlock and initialisation free such that $c \equiv d$.

Conclusions

- The calculus of signal flow diagrams does not rely on flow directionality as a primitive.

The reason why physics has ceased to look for causes is that in fact there are no such things. The law of causality, I believe, like much that passes muster among philosophers, is a relic of a bygone age, surviving, like the monarchy, only because it is erroneously supposed to do no harm.

(Bertrand Russell -1913)

- This allows for a more flexible syntax, disclosing a rich and elegant mathematical playground: IIIH .
- Whenever flow directionality matters, the realisability theorem allows us rewrite any circuit diagram into an executable form.
